IT'S IN THE DETAILS

HANS HAGEN PRAGMA ADE HASSELT NL

Introduction

On the ConTry transition list accordionally a user asks if we can next a several t			
On the $ConT_EXt$ mailing list, occasionally a user asks if we can post a complet		-	1
document with the associated style. One reason for not honouring this request i		-	4
that we want users to cook up their own styles. Besides that, there are a coupl	Э	-	5
of styles in the regular ConT _E Xt distribution.	+	-	6
When browsing through this document, a $ConT_EXt$ user may wonder what styl		-	7
was used to achieve its look and feel. We hope that while reading the text and		_	
playing with the examples, the reader will accomplish the skills to define mor	e	-	9
than just simple layouts.	-		10
This document is not easy reading. Occasionally we spend some time explaining	<u> </u>		
features not described in other manuals. The design of this document is to	а	_ 1	12
large extent determined by its purpose, and as a result not always functiona	1.	_ 1	13
For instance, we typeset on a grid which doesn't look too good. Also the orde	r	_ 1	14
of presenting features, tips and tricks is kind of random and unstructured. Th	e	_ 1	15
idea is that the visual effects will draw you to the right trick. Also, if you reall	ÿ	_ 1	16
want to benefit from these features, there is no way but to read the whole story	7.	_ 1	17
In spite of all its shortcomings, I hope that you enjoy reading this (yet unfinished)	_ 1	18
manual. Keep in mind that this manual is far from finished.		_1	19

Snapping heads

The grid snapper in MkIV is quite different from the one in MkII. For not too complex layouts the old grid snapper was quite ok, but the new one should be a bit more robust. In the old situation the running text was assumed to fit on the grid and the normal baseline skip should do the job in combination with the grid aware spacing features and placement mechanisms like tables and figures. 7 Snapping on a fixed grid is sort of counter intuitive in T_EX because it has an a advanced spacing model with glue. Publishers however love grids so we do need to support it. Of course when complex layouts are involved in a later stage of document preparation the grid is often abandoned. This manual uses the grid but 11 I personally never use the grid. There are better ways to make your document 12

look good and often a grid snapped document doesn't look that great anyway, 13 because all elements should somehow fit in multiples of the line height. 14 The MkIV snapper does more analysis and therefore can compensate for the more 15

nasty cases. Of course it can still fail but we hope to fix those cases when we run 16 into them. Grids are controlled by keywords or a combination of them.

none	don't enlarge	
halfline	enlarge by halfline/halfline	
line	enlarge by line/line	
strut	enlarge by ht/dp (default)	
first	align to top line	
last	align to bottom line	
mindepth	round depth down	
maxdepth	round depth up	
minheight	round height down	
maxheight	round height up	
local	use local interline space	
offset:-3tp	vertical shift within box	
bottom:lines		
top:lines		
box	centers a box rounded upwards (box:.5 -> tolerance)	
min	centers a box rounded downwards	
max	centers a box rounded upwards	
	-	
We combine	these directives in so called grid options:	
	0 1	

\definegridsnapping [yes] [maxheight,maxdepth,strut] 41 42 \definegridsnapping [strict] [maxdepth:0.8,maxheight:0.8,strut] 43 \definegridsnapping [tolerant] [maxdepth:1.2,maxheight:1.2,strut] \definegridsnapping [math] [maxdepth:1.05,maxheight:1.05,strut] 45 \definegridsnapping [top] [minheight,maxdepth,strut] 47 \definegridsnapping [bottom] [maxheight,mindepth,strut]

[maxheight,maxdepth,strut]

[maxheight,maxdepth,strut]

\definegridsnapping [normal]

\definegridsnapping [standard]

\definegridsnapping [both]	[minheight,mindepth,strut]
\definegridsnapping [broad]	[maxheight,maxdepth,strut,0.8]
\definegridsnapping [fit]	[maxheight,maxdepth,strut,1.2]
\definegridsnapping [first]	[first]
\definegridsnapping [last]	[last]
\definegridsnapping [high]	[minheight,maxdepth,none]
\definegridsnapping [one]	[minheight,mindepth]
\definegridsnapping [low]	[maxheight,mindepth,none]
\definegridsnapping [none]	[none]
\definegridsnapping [line]	[line]
\definegridsnapping [strut]	[strut]
\definegridsnapping [box]	[box]
\definegridsnapping [min]	[min]
\definegridsnapping [max]	[max]
	F

\definegridsnapping [middle] [maxheight,maxdepth]

45 46 47

As you can see, keys like maxdepth can take a criterium as extra detail, separated by a colon. These options look obscure and often you need to trial and error a bit to get what you want. This is no real problem because most cases are handles 22 automatically. Only headings and structuring elements that exceed a line height 23 might need some treatment. For instance you might want to be more tolerant 24 for (fractions of) a point overflow or when you know that always a blank follows 25 you can decide to limit the height of some element to a line. Some of the options, 26 like math and middle are used internally.

On the next pages we show how the maxheight and maxdepth fractions work on a sample line.

Pseudo columns

In desk top publishing applications the grid is pretty dominant in defining layouts. On the other hand, T_EX is pretty good defining layouts in terms of relative dimensions. This means that mapping a desk top publishing layout into its T_EX (or Con T_EXt) counterpart takes some effort. For what it's worth, personally I don't like grids that much, specially not in complex documents, unless one makes sure that all elements are suitable sized for the grid used.

We not only have to deal with vertical grids, but also with horizontal ones. Here 9 we focus on the second category. When implementing designs, it is best first to 10 look into the normal page layout areas. For most documents these are sufficient, 11 but occasionally we need a more detailed approach. 12

When playing with grids, you need to make sure that grid snapping is turned on. ¹³ It helps if you turn on the grid so that you can see where things end up. When ¹⁴ a horizontal grid is defined, gray vertical rules show their boundaries. ¹⁵

\setuplayout[grid=yes] \showgrid

The \setuplayout command has a few settings that have to do with so called 1 pseudo columns. These are in no sense related to multi-column typesetting and 2 only play a role in placing text on specific locations.

You can use **\layoutcolumnoffset** for positioning relative to the left boundary of the running text:

\hskip\layoutcolumnoffset{2}{\red Text positioned in column 2!}

Text positioned in column 2!

This mechanism is actually meant to ease the definition of complicated (title) pages where many text and graphic elements need to be anchored at well defined places. The layer mechanism is the most natural candidate for this.

\definelayer [text] \setupbackgrounds [text] [background=text]

When anchoring elements on a layer, you can specify absolute positions using the 39 x and y keys but grid based positioning is possible with the column and line keys. 40 We need to pass grid as location specifier. 41

\setlayer[text][column=1,line=48,location=grid]{these are not}
\setlayer[text][column=2,line=47,location=grid]{real columns}
\setlayer[text][column=3,line=48,location=grid]{but fake ones}

	coduced in later chapters. We position the framed text
n column 2 and at line 48	8. In addition we shift the t <mark>ex</mark> t over the pseudo column
vidth, i.e. we position th	e text at the right of the column. The location specifier
ligns the text left from t	he point of positioning.
When we have set up the	pseudo columns, we have access to a couple of variables:
layoutcolumns	counter number of columns
layoutlines	counter number of gridlines
layoutcolumnwidth	dimension width of one column
layoutcolumnoffset{n}	macro position of column n
This is typically a feature	e that has been there for quite a while but that I forget
bout. It's probably beca	use I never have to use grids myself.
n the examples before we	e used some predefined (font) styles:
\definefont[regular	:1][Regular*default sa 1]
	:2][Regular*default sa 2]
\definefont[regular	:3][Regular*default sa 3]
\definefont[regular	:4][Regular*default sa 4]

Backgrounds behind text

A rather common way to draw attention to a passage, is to add a background. In this chapter we will therefore discuss how to enhance your document with those colorful areas that either or not follow the shape of your paragraph. Be warned: this chapter has so many backgrounds that you might start to dislike them.

In the previous paragraph we demonstrated two important features of the background handler: you can nest backgrounds and backgrounds can be tight or wide. Features like this will often be used in combination with others, like special section headers. The raw coding of the previous paragraph is therefore not representative.

\starttextbackground[intro]

A rather common way to draw attention to a passage, is to add a 13 background. In this chapter we will therefore discuss how to enhance 14 your 15

document with \starttextbackground [subintro] those colorful areas that either

- or not follow the shape of your paragraph. \stoptextbackground\ Be warned: this chapter has so many backgrounds that you might start to
- dislike them.
- \stoptextbackground

The outer background commands is defined as follows:

\definetextbackground [intro]

[backgroundcolor=infogray,

- backgroundoffset=.25cm, frame=off,
- location=paragraph, color=red]

Here, the **paragraph** option ensures that the background covers the width of the body text. The inner background is defined in a similar way, but this time we choose **text** location.

\definetextbackground
 [subintro]
 [backgroundcolor=textgray,
 backgroundoffset=0pt,
 frame=off,
 location=text,
 color=blue]

In this document we use protruding characters (hanging punctuation) so we've the chosen a rather large offset, one that also matches the rest of the page design. Those who are familiar with the way T_EX works will probably see what problems the rest of the page design.

3

41

42

43

45

can occur with backgrounds like this. What happens for instance when we cross page boundaries, and how will more complicated paragraph shapes be handled? The current implementation tries to handle page breaks and paragraph shapes as good as possible. This works well in normal one–column mode as well as in columns.

In this example, the paragraph shape is determined by the graphic placed left of the text. This feature is implemented using the \hangindent and \hangafter primitives, which means that we need to keep track of their state. In addition, we need to handle the indentation directives \leftskip, \rightskip and \parindent. Be-

Figure 3.1

cause backgrounds end up in a different background overlay, nesting_11 them is no problem, and it is even possible to move them to the front $_{12}$ and back, as we will demonstrate later on. While the mechanism discussed here_13

will always be improved when we find border cases, the fundaments it is built $_{14}$ upon are quite stable.

\placefigure[left]{}{\externalfigure[detcow][width=2cm]}

\starttextbackground [A]

In this example, the paragraph shape is determined by the graphic placed

left of the text.

\starttextbackground [B]

This feature is implemented using the \type {\hangindent} and \type

{\hangafter} primitives, which means that we need to keep track of

their state. In addition, we need to handle the indentation directives

\type {\leftskip}, \type {\rightskip} and \type {\parindent}. \stoptextbackground\

> 41 42

43

45

46 47

Because backgrounds end up in a different background overlay, nesting

them is no problem, and it is even possible to move them to the front

and back, as we will demonstrate later on. While the mechanism discussed

here will always be improved when we find border cases, the fundaments

it is built upon are quite stable.

\stoptextbackground

The backgrounds were defined as:

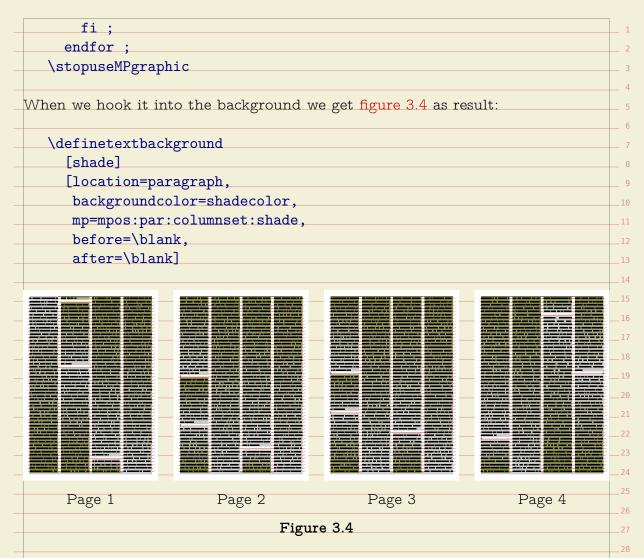

\definetextbackground [A] [backgroundcolor=infogray] \definetextbackground [B] [backgroundcolor=textgray]

\setuptextbackground

The complexity of the backgrounds mechanism is partly due to the fact that we $_{29}$ want to use arbitrary MetaPost code to render the background. For instance, we want to have a proper shape so that not only the filled shape but also the drawn shape comes out right. You can compare this to a glyph in a font: when rendered filled the outline can be anything as it will not be drawn but when we use the outline we can run into overlaps and such. Where glyphs can use the odd-even filling methods, background can only use that for simple cases. When a background is rectangular it's all quite easy but as soon as some holes occur we need to do more work. Holes can be the result of a image placed next to the running text, or an image flushed at a page break or in the middle of a background. Paragraph shapes are another example. Backgrounds can cross page boundaries too. Yet another property is nesting and in such cases the shape is a _ 40 bit more complex as we cross lines partially. In MkII the background mechanism already was quite useable but it had some limitations. Calculating the background was mostly delegated to MetaPost which is reasonable. In MkIV some work is delegated to Lua instead but that doesn't

mean that the code is cleaner or easier to understand. So, to summarize, there are several cases that we need to take into account, like:

A background can run behind a paragraph in which case the start is leftmost

and end rightmost. In this case inserts (like floats) have to be dealt with after the shape has been calculated.

- A background can be in-line (the **text** location variant) in which case we need to follow the paragraph shape, if set. In that case we have a mix of calculating the background shape and afterwards compensating for inserts.
- A third case is tabulation and tables where we have dedicated regions to deal with. When these float we need to make sure that the backgrounds are adapted to the where they end up.

• Yet another case is in columns, where we hape multiple regions to deal with.

As mentioned, floats need special treatment and they can be part of the page 14 flow but also end up left or right of the text (either or not shifted) but also 15 in the margins, edges, back- or cutspace. Their placement influences the way 16 backgrounds are calculated so additional information needs to travel with 17 them.

We distinguish between a paragraph background, which runs between the left and right skip areas and a text background which follows a shape. In figure 3.5 we see a test case with several such shapes.

In the case of side floats the following cases occur. Of course multiple such cases can follow each order so in practice we have to deal with an accumulation.

As often in T_EX coming up with a solution is not a the problem but interference is. You can cook up a solution for one case that fails in another. Backgrounds fall into this category, as do side floats. In the next pages we will demonstrate a few cases. In practice you can probably always come up with something that works out well, but in an automated workflow (like unattended xml to pdf conversion) you can best play safe. We show some examples on the next pages.

Regular (page flow) floats are a different story. Here we have the problem that a float might be postpones because there is no room on the current page and they are moved forward (which is why they're called float). Again we show some examples. 41

_45

_ 46 _ 47 _ 48

Because of its look and feel, a math formula can look too widely spaced when put on a grid. There are a few ways to control this. First of all, the default grid option bound to math is already more tolerant. But you can control it locally too. Take the following formula:

 $a = b^c$

This has been entered as:

a = b^c \stopformula

\startformula

and because it is just a line of math it comes out as expected. The next code

\startformula
 a = \frac {a} {b}
\stopformula

produces a higher line:

 $a = \frac{a}{b}$

as does:

We will now demonstrate three ways to compensate fo rexcessive spacing. The first variant just sets a grid parameter:

4

9

_14

_20

_36

_40 _41

_42 43

_45 _46

```
\startformula[grid=math:-halfline]
    a = \frac {\frac {b} {c}} {\frac {d} {e}}
\stopformula
```

You can also pass this as an option. Only a few such grid related options are defined: halfline, line, -halfline and -grid.

 $a = \frac{\frac{b}{c}}{\frac{d}{e}}$

```
\startformula[-halfline]
    a = \frac {\frac {b} {c}} {\frac {d} {e}}
    \stopformula
```

$$a = \frac{\frac{b}{c}}{\frac{d}{e}}$$

If you need to compensate frequently you can consider defining an instance:

\defineformula[tight] [grid=math:-halfline]

\starttightformula
 a = \frac {\frac {b} {c}} {\frac {d} {e}}
\stoptightformula

$$a = \frac{\frac{b}{c}}{\frac{d}{e}}$$

The result can be somewhat unexpected at the top and bottom of a page. When we subtract half a line from the height we can end up above the text area. This is where the **split** directive comes in. So, the compensations are actually defined as

math	maxdepth:1.05,maxheight:1.05,strut
math:line	maxdepth:1.05,maxheight:1.05,strut,line,split
math:halfline	maxdepth:1.05,maxheight:1.05,strut,halfline,split
math:-line	maxdepth:1.05,maxheight:1.05,strut,-line,split
math:-halfline	maxdepth:1.05,maxheight:1.05,strut,-halfline,split

You can define your own variants building on top of an existing one:

\definegridsnapping[math:my][math,...]

We demonstrate the effect of the **split** directive here. It triggers a check at the 14 page boundaries but you need to keep in mind that this is not always robust as 15 such boundaries themselves can be triggered by and inject anything. 16

$$a = \frac{\frac{b}{c}}{\frac{d}{e}} (\text{top 1 default})$$

$$a = rac{b}{rac{d}{e}}(ext{top 2 default})$$

$$a = \frac{\frac{b}{c}}{\frac{d}{e}}(\text{top 3 default})$$

$$a = rac{b}{rac{d}{e}}(ext{top 4 default})$$

$$a = \frac{\frac{b}{c}}{\frac{d}{e}} (\text{top 5 default})$$

$$a = \frac{\frac{b}{c}}{\frac{d}{e}} (\text{top 6 default})$$

These mechanisms might be improved over time but as we don't use it frequently

These mechanisms might be improved over time but as we don't use it frequently that might take a while.

The following formula was posted at the $ConT_EXt$ mailing list in a grid snapping thread and we will use it to demonstrate how you can mess a bit with the snapping.

 $g(x_{*}) = \lim_{n \to \infty} g(a_{n}) \leq 0 \leq 0 \leq 0 \\ g(b_{n}) = g(x_{*})$

We show the given grid parameter as well as its expansion into the low level grid directives.

$$g(x_*) = \lim_{n \to \infty} g(a_n) \leq 0 \leq \lim_{n \to \infty} g(b_n) = g(x_*)$$

grid=math,nodepth expanded: maxdepth:1.05,maxheight:1.05,strut,nodepth

$$g(x_*) = \lim_{n \to \infty} g(a_n) \leq 0 \leq \lim_{n \to \infty} g(b_n) = g(x_*)$$

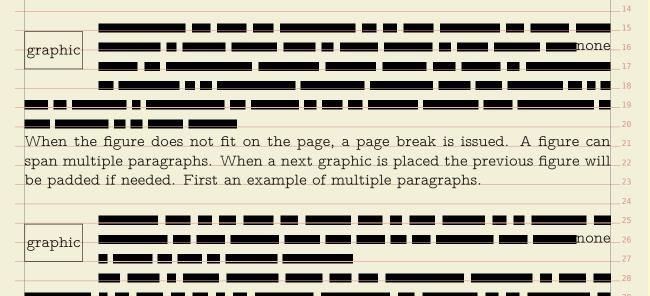

Floating around

Graphics, tables and alike are often treated as floating bodies. This means that when such a body does not fit on the current page, it will be moved to the next one. In the examples we will use figures, but everything we demonstrate here applies to all floats.

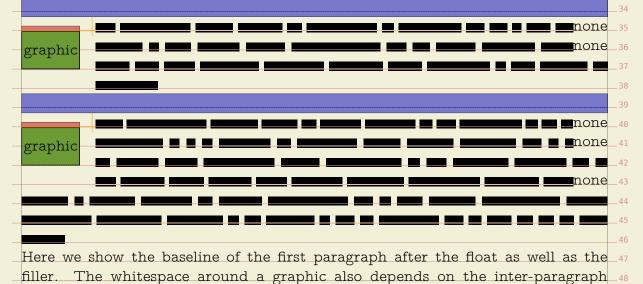

A side float is a float which placement one way or another depends on the text that follows it. In its simplest form, the text flows around it, for instance in:

The first keyword of such a call is treated as a placement directive, so this figure will be placed left. The **none** directive nils the caption.

Multiple floats in a row will lead to padding. The amount of padding is a combination of empty lines and the normal white space following the float. The visual quality of the result depends on the graphic itself.

[edgefig	rurel
	-
[figure]	

\setupfloat

[edgefigure]

```
[leftmargindistance=-\innercombitotal,
```

____default={left,none,low,high}]

The **\innercombitotal** is one of the many available dimensions. This measure is the combined width of the margin and edge.

\placeedgefigure
{} {\framed[width=1.5cm]{!}}

\placeedgefigure
{} {\framed[width=\innercombitotal]{!}}

You need to be aware of the fact that the margins and edges are not related to ²⁵ the backspace and cut space settings. When you set up a layout, you need to ²⁶ think of the right page as starting point. In a double sided layout, the margins ²⁷ are swapped in the page composition stage. Unless you explicitly go to a left or ²⁸ right page, you don't know if your left margin will be swapped or not. ²⁹ For this reason ConT_EXt provides the inner and outer margin/edge dimensions. ³⁰ These are automatically synchronized when the float is constructed. So, if you ³¹ want to automatically adapt the float placement and width to the current left ³² margin in a double sided document, you can use the inner dimensions. ³³

none

 dimension	left page	right page	3!
 \outermarginwidth	\leftmarginwidth	\rightmarginwidth	36
 \innermarginwidth	\rightmarginwidth	\leftmarginwidth	3
 \outermargindistance	\leftmargindistance	\rightmargindistance	38
 \innermargindistance	\rightmargindistance	\leftmargindistance	39

Similar dimensions are available for the edges. You can save yourself some calcu-41 lations by using the following dimensions:

\leftmargintotal	left margin width	+	left margin distance	44	4
Ŭ	U		right margin distance	45	5
	0 0		inner margin distance	46	ô
\outermargintotal	outer margin width	+	outer margin distance	47	7

[criterium=.25\textwidth]

This will automatically turn figures that are wider than 25% of the text width into normal floats instead of side floats. But let's not fall back on that feature now.

You can use **maxwidth** and **minwidth** variables to control the placement in more detail. The exact result depends on the settings of **location**. By default we center, but you can set the location to **left** or **right** to achieve a different alignment.

\definefloat [midmarginfigure] [figure]

\setupfloat

[midmarginfigure]

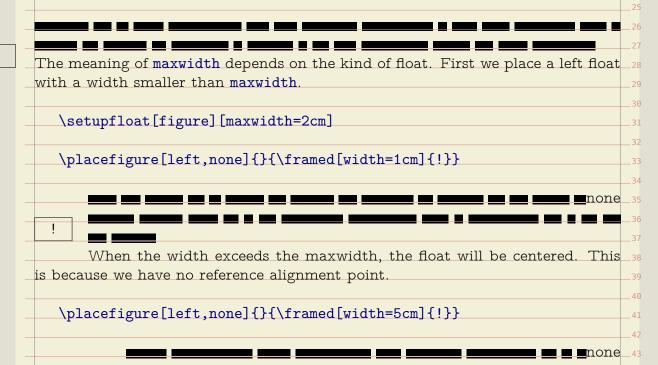

[minwidth=\leftmarginwidth, default={leftmargin,none}]

You can use maxwidth and minwidth variables to control the placement in more 19 detail. The exact result depends on the settings of location. By default we center, 20 but you can set the location to left or right to achieve a different alignment. 21

\placemidmarginfigure
{} {\framed[width=1.5cm]{!}}

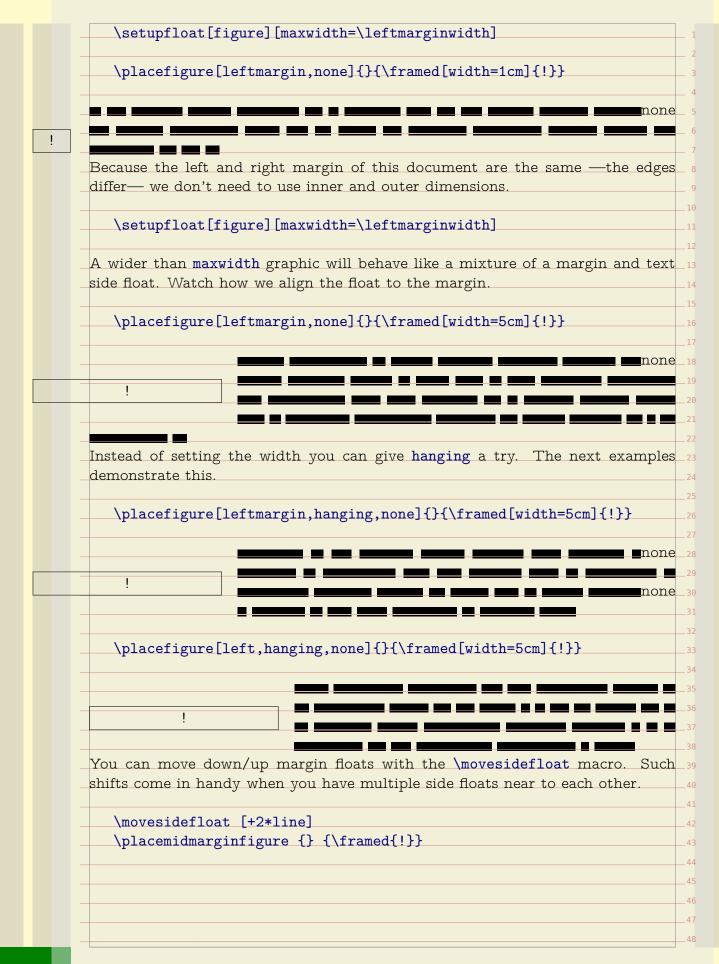

!

Į.

In margin floats, the maxwidth settings have a different result. First we place a 47 small graphic.

ļ

ļ

Did we clash or not?

Do we clash or not?

Did we clash or not?

There are a few macros that can be of help with solving clashes in side floats:

8

_ 14

41

- 42 43

47

48

\flushsidefloats This macro moves down as much as is needed to separate the side floats of each other.

forgetsidefloats this macro kind of forgets that a side float is in progress.

Use these macros with care. If you change the dimensions of the graphic and/or 10 content involved, reconsider the use of these directives.

The next couple of spreads we will demonstrate some example definitions. These 21 placements are taken from one of the styles we made for typesetting a series of 22 school math books which illustrations and tables all over the pages. 23 First we fine tune the spacing around side floats and verbatim text. 24

\setupfloats
[sidespacebefore=none,
 sidespaceafter=depth]

\setuptyping [margin=]

The placements have rather verbose names. In this case the word 'edge' is used to identify bleeding floats (with an cut-off margin of 3mm). The 'text' floats are side floats positioned in the main text flow.

\setupfloats
[sidespacebefore=none,
 sidespaceafter=depth]

\setuptyping [margin=]

Watch how we define fall backs for too wide content (criterium as well as use maxwidth to manipulate the placement of content that falls off the margins. The black rules are set up with:

\setupblackrules[color=tred,depth=0pt,height=1.5cm]

We will now demonstrate some features in a way that makes it possible to compare to the simple default case. Options can be passed as keywords:

4

8

_14

_40 _41

43

_45 _46 _47

\placefigure
 [left,...]
 [fig:whatever]
 {caption}
 {content}

or as settings:

\startplacefigure
 [default={left,...},
 title=caption,

reference=fig:whatever]

content

\stopplacefigure

It is important to realize that all that spacing can interfere with additional hard coded corrections at the users end. We don't show the effects of sidespacebefore and sidespaceafter, the two general vertical spacing hooks. These are currently set to big and big respectively. The sidealign parameter is always winning from a keyword doing the same.

The last few examples demonstrate that you can define an instance. Often that's the best way to deal with special cases in a consistent way. For instance: 27

\definefloat	
[LeftTwo]	
[figure]	
L03	

\setupfloat
 [LeftTwo]
 [default=left,
 sidealign=line]

First we show some keyword variant, next some parameter driven versions.

Agriculture is a fairly recent human invention, and in many ways it was one of the great stupid moves of all time. Hunter-gatherers have thousands of wild sources of food to subsist on. Agriculture changed that all, generating an overwhelming reliance on a few dozen domesticated food sources, making you extremely vulnerable to the next famine, the next locust infestation, the next potato blight. Agriculture allowed for stockpilling of surplus resources and thus, inevitably, the unequal stockpiling of them — stratification of society and the invention of classes. Thus, it allowed for the invention of poverty. I think that the punch line of the primate-human

difference is that when humans invented poverty, they came up with a way of subjugating the lowranking like nothing ever seen before in the primate world. Agriculture is a fairly recent human invention, and in many ways it was one of the great stupid moves of all time. Hunter-gatherers have thousands of wild sources of food to subsist on. Agriculture changed that all, generating an overwhelming reliance on a few dozen domesticated food sources, making you extremely vulnerable to the next famine, the next locust infestation, the next potato blight. Agriculture allowed for stockpilling of surplus resources and thus, invertably, the unequal stockpilling of them — stratification of society and the invention of classes. Thus, it allowed for the invention of poverty. Finetuning graphics

.14

In this chapter we will discuss a few more tricks to control float placement. This control is needed if you want to typeset documents in a semi desk top publishing way.

When you combine technical graphics, you may wish to align the content optically. 6 This can be done with the **offset** command. We will demonstrate this with a couple of MetaPost graphics:

\startreusableMPgraphic{alpha}

fill fullsquare xyscaled(2cm, 2cm) withcolor \MPcolor{red} ;
fill unitsquare xyscaled(+.5cm,+.5cm) withcolor \MPcolor{gray} ;
\stopreusableMPgraphic

\startreusableMPgraphic{beta}

```
fill fullsquare xyscaled( 2cm, 2cm) withcolor \MPcolor{red} ;
fill unitsquare xyscaled(+.5cm,-.5cm) withcolor \MPcolor{gray} ;
\stopreusableMPgraphic
```

\startreusableMPgraphic{gamma}

fill fullsquare xyscaled(2cm, 2cm) withcolor \MPcolor{red} ;
fill unitsquare xyscaled(-.5cm,-.5cm) withcolor \MPcolor{gray} ;
\stopreusableMPgraphic

\startuseMPgraphic{delta}

```
fill fullsquare xyscaled( 2cm, 2cm) withcolor \MPcolor{red} ;
fill unitsquare xyscaled(-.5cm,+.5cm) withcolor \MPcolor{gray} ;
\stopuseMPgraphic
```

\startcombination[2*2]
 {\reuseMPgraphic{alpha}} {alpha}
 {\reuseMPgraphic {beta}} {beta}
 {\reuseMPgraphic{gamma}} {gamma}
 {\reuseMPgraphic{delta}} {delta}
\stopcombination

In figure 6.1 we place these graphics in a 2*2 grid. As you can see, the centers don't align well.

In figure 6.2 the centers of the graphic align well. This is accomplished by adding 39 some space around the graphics. 40

\startcombination[2*2]

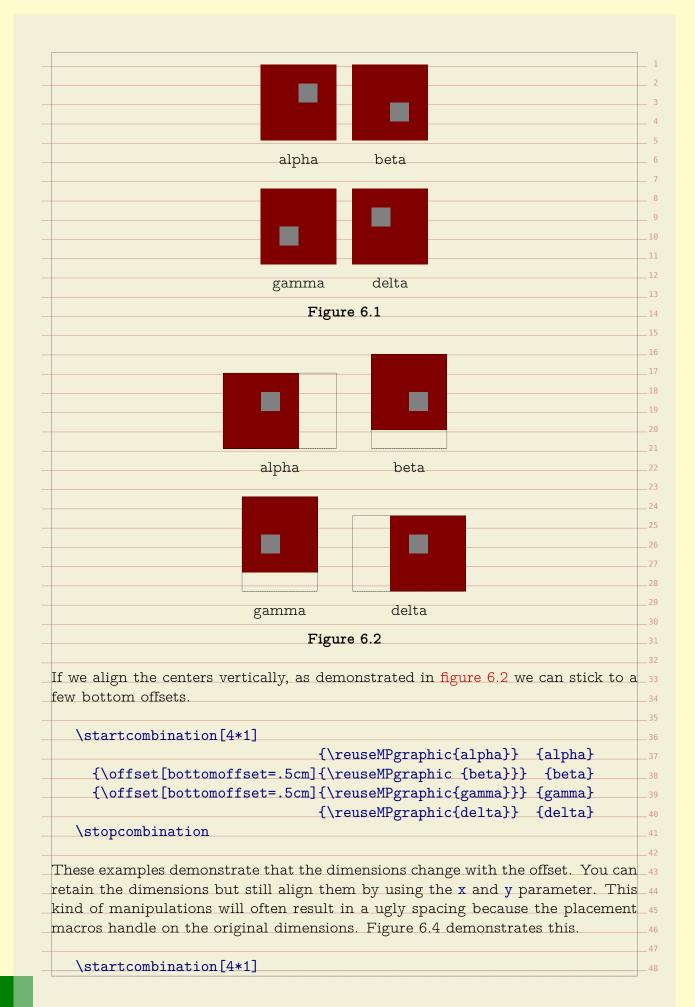

15

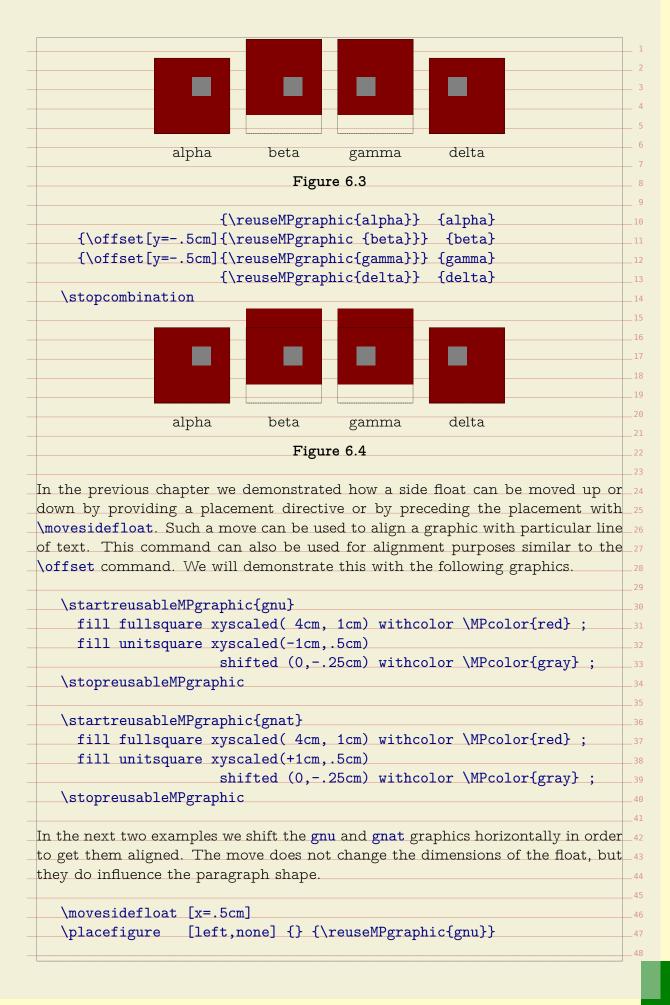

{\offset[rightoffset=1cm] {\reuseMPgraphic{alpha}}} {alpha}	
{\offset[bottomoffset=.5cm]{\reuseMPgraphic {beta}}} {beta}	
{\offset[bottomoffset=.5cm]{\reuseMPgraphic{gamma}}} {gamma}	
{\offset[leftoffset=1cm] {\reuseMPgraphic{delta}}} {delta}	
stopcombination

41

42 43

_45 _46

for instance that the available room equals the text height minus the height of the text so far. You can slightly influence the way these values are interpreted by setting the calculation method. You can set the methods as follows:

\setupfloats[textmethod=0,sidemethod=1]

Method 0 just looks at the raw dimensions, while method 1 lessens the maximum text height by one percent, thereby playing safe. Method 2 takes a window of 1 point. This may lead to better decisions since we may run into rounding errors of several scaled points (which is small but troublesome). Method 2 is well suited when typesetting on a grid, because there everything has to fit in a rounded number of lines, which leaves no room for rounding errors.

grid modeyesnosidemethod21textmethod20

As you may know by now, we can use the directives high, low, height, depth and line to influence the spacing around a side float. A real tight spacing can be achieved with fit.

\placefigure[left,fit,none]{}{some graphic}

This kind of placements only make sense in special situations, 25 because normally you don't want the graphic to touch the text. If you think that this is all a user may want, you're wrong. It is not imaginary 27 that graphics have small piezes sticking out and (or late of white space as part of

that graphics have small pieces sticking out and/or lots of white space as part of their design. In that case, the bounding box can be set to a smaller size.

Now, when handling a side float, ConT_EXt first places the float, 31 and then starts with typesetting the paragraph, cleverly avoiding 32 the graphic. However, when the graphic is virtually larger than its known size, it 33

may cover part of the preceding paragraph.

How come that the graphic starting this paragraph does not do that? It is because we explicitly moved it to the background. This involves some preparation. At the document level, we define a layer called **graphic**.

\definelayer[graphics][position=yes]

The position directive tells $ConT_EXt$ that it should honour the position of the graphic. Next we must make sure that this layer is placed.

\setupbackgounds[page][background=graphics]

Now we're ready to move graphics to this layer:

\placefigure

43

45

[left,fit,none] {}{\setlayer[graphics]{graphic}}

It's now a small step to more advanced movements. Say that you want to move the graphic a little bit to the left. In that case you can tell the layer placement to do so.

\placefigure
 [left,fit,none]{}{\setlayer[graphics][hoffset=-12pt]{graphic}}

From this you can deduce that there is also a movement in the vertical direc-11 tion using **voffset**. In addition you can anchor the graphic using the **location** 12 parameter and provide offsets.

As soon as you run into situations where float placement is to be consistently enforced, you will feel the need for dedicate place- 16 ment macros. For example:

14

	18
\definefloat	19
[somefloat]	20
[figure]	21
	22
\setupfloat	23
[somefloat]	24
[sidespaceafter=,	25
sidespacebefore=,	26
default={left,none}]	27
	28
Instead of resetting the side spacing, we could have default to high, low, but this	29

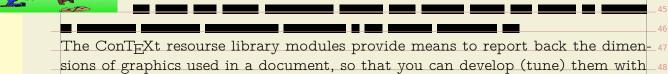

way we can overload the default placement and still get zero spacing. Throughout this manual we discuss features related to overlays and layers. These

permit you to move content around in ways that either or not depend on the text flow. We have now come to another trick based on these mechanisms: bleeding. When printing a document, you need to take into account that when graphics go beyond the page boundary, you need to compensate for inaccuracies in cutting the pages. Such graphics are called bleeding graphics and the amount of bleed is often a few millimeters.

The best way to handle such graphics is to use the correct dimensions and play 38 with the edge widths and distances in combination with backspace and cut space. 39 In a properly set up layout and by using a well designed set of predefined graphic 40 placements, you can handle this quite well. A bleeding figure can be defined as 41 follows: 42

	43	
\definefloat	44	
	45	
[edgefigure] [figure]	46	
\setupfloat	47	
(Secupitoat	48	

	ault={inner,height,high,low,none}, vidth=4cm]
mert	
	externalfigure
	efigure]
	<pre>ch=\dimexpr\backspace+4cm-1mm\relax,</pre>
line	es=4]
The defaul	t placement is pre-configured to have no additional vertical space ar
align on th	e height of a line (this is default behaviour so the height key is redu
	The 1mm in the previous definition simulates what happens when
page is cut	off slightly wrong: we get an annoying gap.

_43 _44

none

none

the proper dimensions. In practice a slightly wider than normal graphic (scaling it horizontally a few millimeters more) does not harm the visual appearance that much, so adapting a graphic to this kind of bleeding is not really needed. In addition to this (rather natural) way of adding bleed to a graphic, you can apply the **bleed** macro. In the previously discussed method the figure placement mechanisms work with the real dimensions. The **bleed** macro is using scaling in a different way: from the perspective of ConTEXt the graphic remains its original dimensions and the figure placement mechanisms will act accordingly. We will give a couple of examples of using this macro.

\placesomefloat
 [left,none,fit]
 {}

{\setupbleeding[offset=5mm]%

\bleed[width=5cm,height=1cm,location=1]
 {\externalfigure[mill][bleed]}}

 \placesomefloat

[left,none,fit]
{}

{\setupbleeding[offset=2mm]%

\bleed[width=5cm,height=1cm,location=1]
{\externalfigure[mill][bleed]}}

The amount of bleeding depends on the postprocessing. In the previous paragraph 39 we used a bleed offset of 5mm, and here we used 2mm. Because the graphic is 40 scaled in order to match the bleed, it will be slightly distorted. With small values 41 this will go unnoticed. You can set the offset with: 42

43

45

47

\setupbleeding[offset=5mm]

Bleeding itself is accomplished by the **\bleed** macro as in:

\bleed

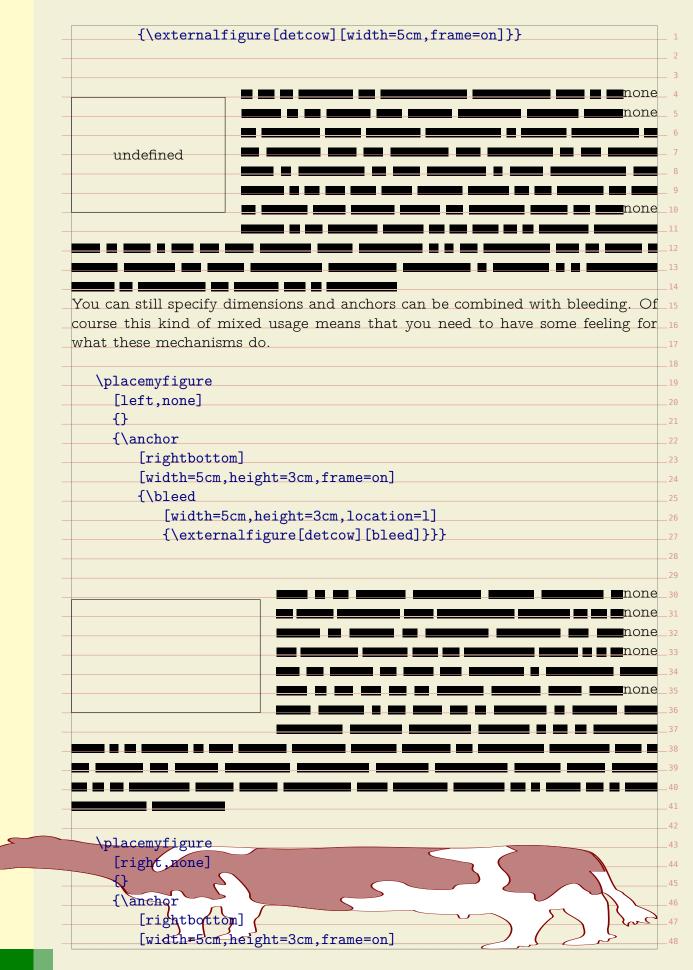

[width=5cm, height=1cm, location=1] {\externalfigure[mill][width=\bleedwidth,height=\bleedheight]} It is kind of awkward to pass those two dimensions so here is a shorter way of doing the same: \bleed [width=5cm, height=1cm, location=1] {\externalfigure[mill][bleed]} In fact, this uses the following definition: \defineexternalfigure[bleed][width=\bleedwidth,height=\bleedheight] You can influence the scaling of a graphic by setting the stretch parameters. 15 The location parameter determines the direction of the stretch: 1 (left), r (right), 16 t (top), b (bottom) or a combination of these. We will now combine the previous 17 example code with this knowledge. \placefigure [left] {} {\bleed [stretch=no,voffset=0pt,hoffset=1cm] {\externalfigure[detcow][bleed]}} ne none one Figure 6.5 \placefigure [left] {} 41 {\bleed 42 [width=5cm,height=3cm,location=1] 43

Ornaments everywhere

14

The background mechanisms present in ConT_EXt have evolved over time and with computers becoming faster, you can expect new functionality to show up and existing functionality to start using this technology. A simple background consist of a colored area. Many commands accept settings like:

...[background=color,backgroundcolor=red,backgroundoffset=3pt]

Instead of such an area you can define one or more so called overlays:

\defineoverlay[one][...] \defineoverlay[two][...]

...[background={one,two}]

The name overlay comes from the fact that you stack them on top of each other. 17 A special overlay is **foreground**, and deep down in ConT_EXt there are more more predefined overlays. 19

In the MetaFun manual you will find example of usage, so here we stick to a simple code snippet for testing this functionality:

\defineoverlay[one][\green A]
\defineoverlay[two][\red B]

\framed[background=one] {1}
\framed[background={one,two}] {1---2}

The rather ugly result is:

▲ 1-1-2

You can construct overlays by using T_EX boxing primitives or commands like **framed**. Alternatively you can use another mechanism: layers. Layers collect content and flush that when asked, for instance when an overlay is constructed. Layers can be independent of a page, or bound to a specific page number, left or right hand pages. Here we look at independent layers. 32

All these mechanisms are fine tuned for cooperating with the output routine (the $_{37}$ part of T_EX that deals with composing pages) and are well interact quite well $_{38}$ with MetaPost graphics. Details of usage and tricks are revealed in this manual $_{39}$ as well as in styles that come with ConT_EXt. In this chapter we will apply layers to graphics. For this we need a few setups, like:

\setupbackgrounds [page]

[background=pagegraphics]

Here we have set up the page background to use an overlay called **pagegraphics**. 47 However, instead of an overlay, we will use a layer. This layer will collect content

42

that goes into the page background. Whenever a layer is defined, an overlay is automatically defined as well.

\definelayer

[pagegraphics]
[x=-2mm, 200
y=-2mm,
width=\paperwidth,

height=\paperheight]

When you fill a layer with content, you can influence the placement with the x 11 and y parameters as well as hoffset and voffset, whichever you prefer. The 12 reference point and alignment are set with corner and location. 13

Live can be made easier by using presets, especially for our intended usage. The 14 following presets are predefined.

\definelayerpreset

[lefttop] [corner={left,top}, location={right,bottom}]
\definelayerpreset

[righttop] [corner={right,top}, location={left,bottom}]
\definelayerpreset

[leftbottom] [corner={left,bottom}, location={right,top}] \definelayerpreset

[rightbottom] [corner={right,bottom},location={left,top}]

Because for this layer we have also preset the x and y, those corners are laying a few millimeters outside the page area. We have preset the size as well, otherwise and corners would end up in the top left corner.

We will now fill this layer. Because the layer is hooked into the page, it will be flushed when the page is constructed. After the page is written to the output file, 30 the layer is emptied, unless its state is set to repeat. 31

\setlaver [ex	xtras] [preset=le	efttop] {\exte	ernalfigure[hacker]}	33
•	xtras] [preset=ri	-	ernalfigure[hacker]}	34
· ·	-	u	ernalfigure[hacker]}	35
· ·	-		ernalfigure[hacker]}	36
(Sectayer Lev	kulasj [preset-ri	ranchorcoml (levce	Inall Ignie [nacker]]	-

Once you got the picture of layering, you will start using this mechanism for all kind of tasks. Instead of putting layers in a background, you can also directly place them, by using one of the two (equivalent) commands:

\composedlayer{identifier}
\placelayer[identifier]

Layer are quite convenient for defining title pages, colophons, and special section heads, especially in combination with \framed.

On top of the layer mechanism we have build a few more mechanisms, like ornaments. You can use ornaments to annotate graphics in such a way that the dimensions stay unchanged. \defineornament [affiliation] [rotation=90,corner={right,bottom},location={right,top}, hoffset=-.25ex] [frame=on, background=color, backgroundcolor=red, offset=0pt] The negative offset will overlay the text outside the graphic. The meaning of the sign of coordinates and offsets depends on the corner. Figure 7.1 shows the result. 10 We have put the reference point in the right bottom corner. The ornament is 11 anchored at the right top corner of the dot you can picture at the reference point. 12 The ornament is shifted .25ex outwards. \placefigure {} {\affiliation{graphic}{\externalfigure[hacker][width=3cm]}} Figure 7.1 Number 1 There are two ways to handle the placement. Alternative a will change the 26 dimensions of the graphic according to the size of the ornament, while alternative 27 b acts as a pure overlay. In figure 7.2 the ornament is not taken into account when 28 calculating the dimensions of the graphic. This is often the preferred placement, 29 because this way the (often small) ornament will not it will not spoil visual alignment of similar graphics. \defineornament [affiliation] [rotation=90,corner={right,bottom},location={right,top}, hoffset=-.25ex,alternative=b] [frame=on, background=color, backgroundcolor=red, offset=0pt] 41 42 43 Figure 7.2 Number 2

A positive offset will place the ornament on top of the graphic (see figure 7.3).

graphic

There are several methods to construct title pages, headers, and other compositions. Of course there are the low level box constructors like **\hbox**, **\vbox** and 43 positioning primitives like **\hskip**, **\hfill** and alike. 44

Another option is to fall back on the low level box macros in the $ConT_EXt$ support 45 file supp-box or the higher level \framed macro. You can use \framed nested and 46 by cleverly using the offsets and dimensions you can do a lot. 47

Layers are another means. You can or instance construct a title page in the 48

\ definelerrer	
\definelayer	+
[titlepage]	+
[width=\textwidth,	+
height=\textheight]	+
\setlayer	
[titlepage]	
[preset=righttop,location={left,bottom},y=1cm,x=1cm]	
{\definedfont[Regular at 60pt]Welcome}	
\setlayer	
[titlepage]	
[preset=rightbottom,location={right,top},y=2cm,x=2cm]	
{\definedfont[Regular at 30pt]By Me}	
This just fills the layer. Placement is done with:	
\startstandardmakeup	-

	+
The second se	
\setcollector[test]	

x, y, offset, hoffset and voffset for positioning and rotation for (as expected) rotating the content in steps of 90 degrees. As with layers, the coordinates and offsets can be used intermixed. \setcollector[test] [hoffset=4cm, voffset=-1cm, corner=middle, location=middle] {\framed{now}} a dutch cow now .14 nearly done this is a con that's for sure We can show the intermediate results because we have set the state of this collec- 20 tor to repeat. In this case you need to erase the content manually, using: \resetcollector[test] The chapter titles of this document are (as usual in a $m ConT_EXt$ document) typeset by the Γ macro. When thinking about implementing a non standard head, 26 those familiar with ConT_FXt's head macros will probably first think of using one of the hooks, like: \setuphead[chapter][command=\MyChapterHead] Here we have followed a different approach. First we set up the chapter head. 32 The empty directive instructs ConT_FXt not to place the head itself, but still to $_{33}$ include the associated data in the text stream. This means that we will not see a chapter title, but that there will be an entry in the table of contents, that references will be set up, that so called marks will be available, etc. \setuphead [chapter] [placehead=empty, header=chapter, 41 style=\BigText, 42 numberstyle=\BigNumber] 43 The header parameters instructs the head handler to mark this page as special _45 with regards to header texts. This text is set up as follows: 46 47 \definetext

[chapter]	1
[chapter] [header]	2
[\setups{chapter}]	3
	4

The setups are just series of typesetting instructions. For the sake of readability, 6 we have split them up.

8

9

_14

_16

_20

_48

\startsetups chapter
 \setups[chapter:title]
 \setups[chapter:number]
 \setups[chapter:finish]
 \stopsetups

The setups will use a dedicated layer for the chapter title:

\definelayer
[chapter]
[width=\dimexpr\makeupwidth+\cutspace\relax,
 height=\headerheight]

The following code uses a macro \setlayerframed. This is a combination between 22 \setlayer and \framed. We use two placement macros to typeset the title and 23 number. When doing so, we need to take care of both numbered chapters and 24 unnumbered titles. 25

\startsetups chapter:title

\setlayerframed	29

Grid trickery

.14

In this manual we pay quite some words on ways to snap your content on a grid. When dealing with grids, we often run into conflicting situations where we have to make the best of it. Let's again deal with an aspect of graphics.

One of the strong points of T_EX is that it can deal with graphics automatically, 6 which means that you seldom have to tweak dimensions or placements unless ... 7 you're dealing with grids. In that case you need to make sure that the height of 8

graphics consistently match the height of lines (or multiples of lines). It is for this purpose that the graphic inclusion macro has a grid entry.

We will illustrate its usage using a dedicated figure class where we have set the space between figure and caption to zero.

\definefloat[tightfigure][tightfigures][figure] \setupcaption[tightfigure][inbetween=]

The **grid** parameter controls rounding of the height of a graphic in the following way:

yes	safe rounding to an equal number of lines
fit	tight rounding to an equal number of lines
height	same as yes but incremented by linedepth

On the next pages we demonstrate the effects of these settings. At the bottom ² of a page we show the placement commands. On the last pages we've hidden the ² captions with:

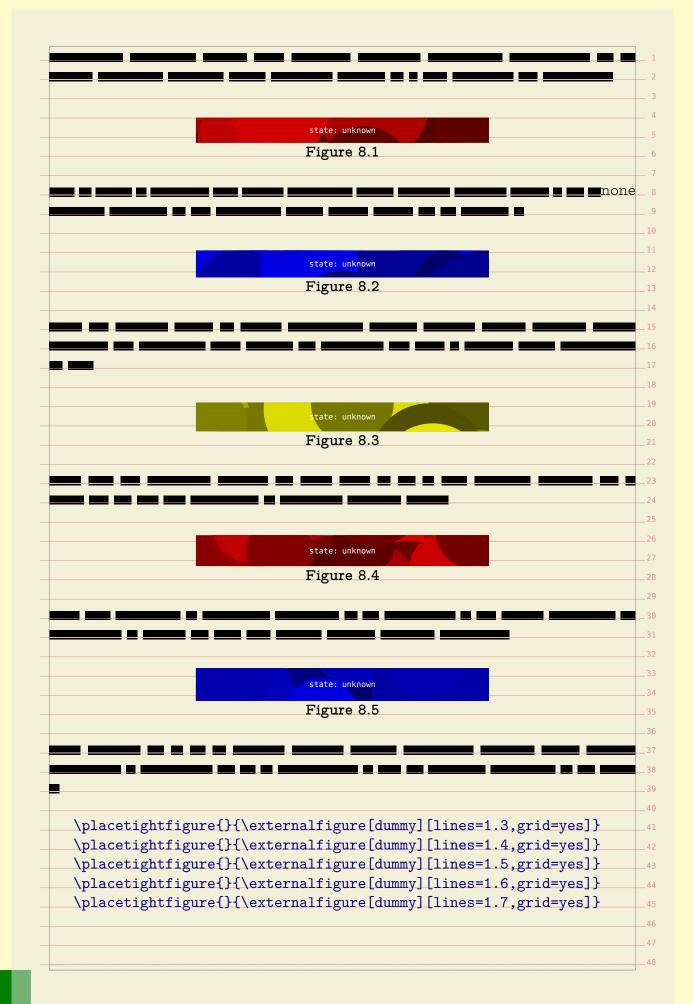

\setupfloat[tightfigure][default={here,none}]

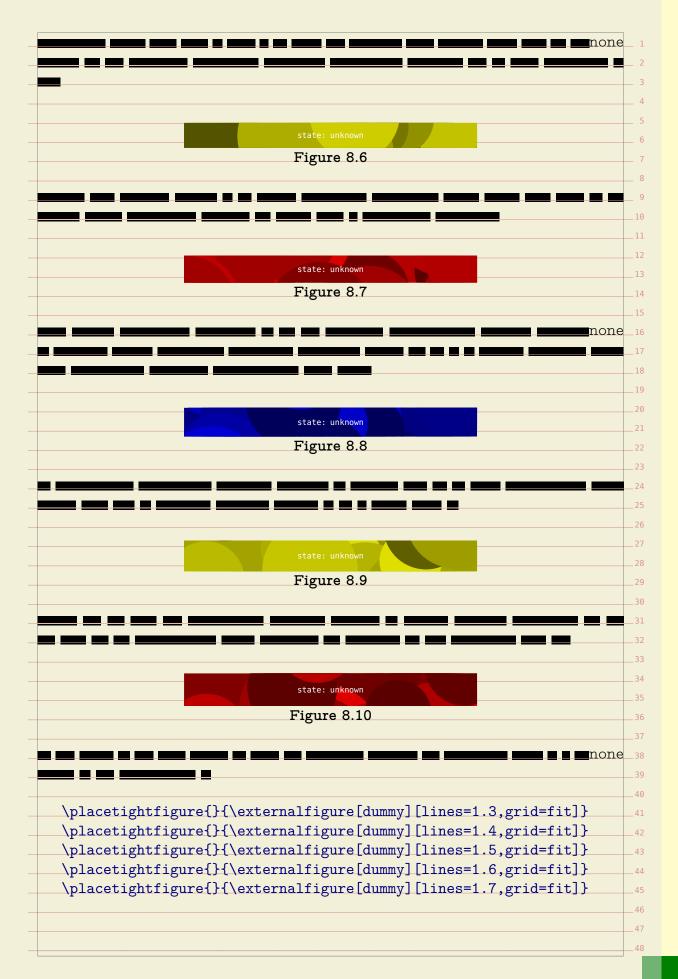

As you will notice, the **height** option is handy when the caption is positioned directly under the graphic.

Caption handling

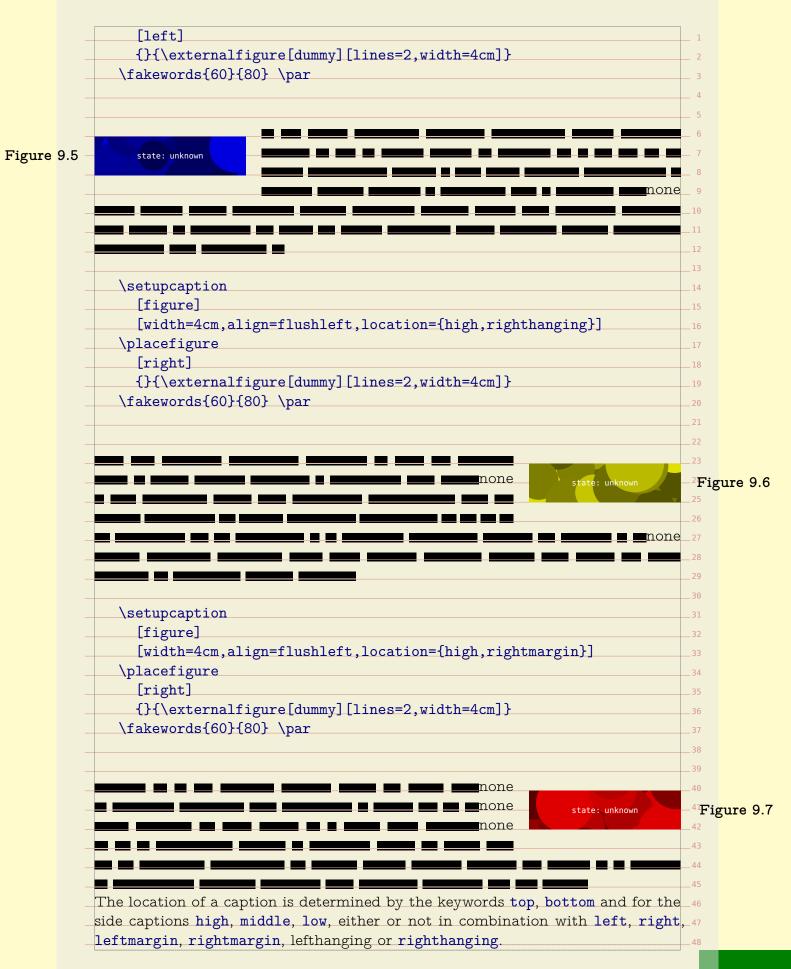

It's hard to predict what kind of caption placements users want. The amount of variation if large and thereby any system of specifying them will look complex. So, examples are the best way to show them.

About this document

This document is typeset in	ConTEXt using LuaTEX with MetaPost. We use only
one font: the Computer Ma	odern Typewriter. The verbatim portions of the text
-	ed variant. One of the reasons that I chose this font is
	l font to typeset the example code, and the Computer
-	
01	the best there is. This font combines well with many
01	metimes excessive use of different fonts (and sizes) in
<i>v i</i>	plement made me long for simplicity. And so I decided
o stick to one font. A caref	ul reader will notice that this document has character
rotruding enabled (resulting the second s	ng in hanging punctuation).
0	Again, I went for simplicity and use rather primary
-	lem in transparent variants as well.
0	-
	say, apart from that I want to thank our customers
—	or asking me to implement dtp competing styles and
eatures. Their demands dr	ive $ConT_EXt$ in directions we could not have foreseen
when we started its develop	oment.
-	ay background behind the text so that we have an
	rea is positioned relative to the page. It also enables
s to comfortably turn on t	8
	are relatively new and therefore they occasionally are
nproved. As a result some	e aspects of their functionality may change.
